Regularization of Fracture Energy

We propose a localization parameter:

$$\kappa_c = \begin{cases} 
\frac{1}{(n_i+n_o)} \left[ \frac{(n_i+n_o+1) \cdot \max_{k \leq n_o+n_i} (\phi_k)}{\sum_{k=0}^{n_i+n_o} \phi_k} - 1 \right], & \text{if } \phi_0 > 0 \\
0, & \text{if } \phi_0 = 0
\end{cases}$$

with a phenomenological transitional function for energy regularization

$$\gamma = \gamma_0 f(\kappa_c) \quad f(\kappa_c) = \frac{h_c}{h_e} + \left(1 - \frac{h_c}{h_e}\right) \exp \left(-\frac{\kappa_c}{\kappa_{0c}}\right)$$

![Diagram showing the transition from distributed to localized damage](image)

Berthier et al. JMPS, 2017
Damage model — incipient of localization occurs around the peak strength (Jirásek 2007).

The location of the localization band is determined by the material strength, which naturally exhibits certain spatial randomness.

Strength distribution of a material element of size $h_e$:

$$P(f_t) = Pr(f'_t \leq f_t) = 1 - [1 - P_1(f_t)]^{n_e}$$

$P_1(f_t) = \text{strength distribution of a single localization band}$

$n_e = \text{equivalent number of potential localization band in the element}$

Probabilistic Treatment of Random Onset of Localization Band

Strength distribution of a material element of size $h_c$ (Bažant et al. 2009; Le et al. 2011; Bažant and Le 2017)

\[
P_1(\sigma) = 1 - \exp\left[-\left(\frac{\sigma}{s_0}\right)^m\right] \quad (\sigma < \sigma_{gr})
\]
\[
P_1(\sigma) = P_{gr} + \frac{rf}{\sqrt{2\pi}\delta_G} \int_{\sigma_{gr}}^{\sigma} e^{-\left(\sigma' - \mu_G\right)^2/2\delta_G^2} d\sigma' \quad (\sigma \geq \sigma_{gr})
\]

The number of potential crack bands is governed by the localization level

![Diagram showing the number of potential crack bands being realistic and unrealistic](image-url)
Probabilistic Treatment of Random Onset of Localization Band

Number of potential crack bands

\[ n_e = 1 + \left( \frac{h_e}{h_c} - 1 \right) \exp \left( -\frac{\kappa_w}{\kappa_{0w}} \right) \]

\( \kappa_w \) measures the level of localization in the neighborhood

\[ \kappa_w = \frac{1}{n_o - 1} \left[ n_o \cdot \frac{\max_{k=n_i+1} \phi_k}{\sum_{k=n_i+1} \phi_k} - 1 \right] \]
Probabilistic Crack Band Model

1. Regularization of fracture energy — transition from damage initiation to localization

\[ F_\gamma(x) = F_{G_f}[xh_c/f(\kappa_c)] \]

2. Probabilistic treatment of randomness of localization band — nonlocal information to determine the applicability of the weakest link model

\[ P(f_t) = 1 - [1 - P_1(f_t)]^{n_e} \]

\[ n_e = 1 + \left( \frac{h_e}{h_c} - 1 \right) \exp \left( -\frac{\kappa_w}{\kappa_0w} \right) \]
Implications of Probabilistic Crack Band Model

Depending on the localization level, the input probability distribution of tensile strength varies with the mesh size — transitioning from a Gaussian cdf to a Weibull cdf.
